Abstract

The conjugate gradient method for unconstrained optimization problems varies with a scalar. In this note, a general condition concerning the scalar is given, which ensures the global convergence of the method in the case of strong Wolfe line searches. It is also discussed how to use the result to obtain the convergence of the famous Fletcher-Reeves, and Polak-Ribiére-Polyak conjugate gradient methods. That the condition cannot be relaxed in some sense is mentioned.

Key words: unconstrained optimization, conjugate gradient, line search, global convergence.

1. Introduction

The conjugate gradient method is highly useful for minimizing a smooth function of \( n \) variables,

\[
\min_{x \in \mathbb{R}^n} f(x),
\]

(1.1)
especially when \( n \) is large. It has the following form

\[
x_{k+1} = x_k + \alpha_k d_k,
\]

(1.2)
\[
d_k = \begin{cases} 
  -g_k, & \text{for } k = 1; \\
  -g_k + \beta_k d_{k-1}, & \text{for } k \geq 2,
\end{cases}
\]

(1.3)

where \( g_k = \nabla f(x_k) \), \( \alpha_k \) is a stepsize obtained by a one-dimensional line search and \( \beta_k \) is a scalar. Because \( \alpha_k \) is not the exact one-dimensional minimizer in practice and \( f \) is not a quadratic, many formulas have been proposed to compute the scalar \( \beta_k \). Two well-known formulas for \( \beta_k \) are called the Fletcher-Reeves (FR), and Polak-Ribiére-Polyak (PRP) formulas (see [8, 16, 17]). They are given by

\[
\beta_k^{FR} = \|g_k\|^2 / \|g_{k-1}\|^2
\]

(1.4)
and

\[
\beta_k^{PRP} = g_k^T (g_k - g_{k-1}) / \|g_{k-1}\|^2
\]

(1.5)
respectively, where \( \| \cdot \| \) means the Euclidean norm. See Dai & Yuan [2], Daniel [6], Fletcher [7], Hestenes & Stiefel [11], Liu & Storey [13] etc. for other formulas of \( \beta_k \).

In recent years, many authors studied the nonlinear conjugate gradient method especially from the angle of global convergence. Because its properties can be very different with the choice of \( \beta_k \) (see Powell [14]), the nonlinear conjugate gradient method was often analyzed

individually, for example, see Al-Baali [1], Dai & Yuan [3, 4], Gilbert & Nocedal [9], Grippo & Lucidi [10], Liu et al [12], Powell [15], Qi [19] and Touati-Ahmed & Storey [20]. Dai et al [5] studied the general conjugate gradient method in the absence of the sufficient descent condition and proposed a sufficient condition ensuring the global convergence (see also Lemma 2.3). Since the nonlinear conjugate gradient method varies with the choice of $\beta_k$, we wonder what condition on $\beta_k$ guarantees the convergence of the method.

This paper is organized as follows. After giving some preliminaries in the next section, we will prove in Section 3 that a mild condition on $\beta_k$ results in global convergence of the nonlinear conjugate gradient method in the case of strong Wolfe line searches. Section 4 discusses how to use the result to obtain the convergence of the famous FR, and PRP conjugate gradient method. In the last section, it is mentioned that the condition on $\beta_k$ cannot be relaxed in some sense.

2. Preliminaries

For convenience, we assume that $g_k \neq 0$ for all $k$, for otherwise a stationary point has been found. We give the following basic assumption on the objective function.

Assumption 2.1. (i) The level set $\mathcal{L} = \{x \in \mathbb{R}^n : f(x) \leq f(x_1)\}$ is bounded; (ii) In some neighborhood $\mathcal{N}$ of $\mathcal{L}$, $f$ is differentiable and its gradient $g$ is Lipschitz continuous, namely, there exists a constant $L > 0$ such that

$$\|g(x) - g(\hat{x})\| \leq L\|x - \hat{x}\|, \quad \text{for any } x, \hat{x} \in \mathcal{N}. \quad (2.1)$$

Assumption 2.1 implies that there exists a constant $\overline{\gamma}$ such that

$$\|g(x)\| \leq \overline{\gamma}, \quad \text{for all } x \in \mathcal{L}. \quad (2.2)$$

The stepsize $\alpha_k$ in (1.2) is computed by carrying out certain line searches. The Wolfe line search [21] is to find a positive stepsize $\alpha_k$ such that

$$f(x_k + \alpha_k d_k) - f(x_k) \leq \delta \alpha_k g_k^T d_k, \quad (2.3)$$

$$g(x_k + \alpha_k d_k)^T d_k \geq \sigma g_k^T d_k, \quad (2.4)$$

where $0 < \delta < \sigma < 1$. Under Assumption 2.1 on $f$, we state the following result, which was essentially obtained by Zoutendijk [23] and Wolfe [21, 22].

Lemma 2.2. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any iterative method (1.2), where $d_k$ is a descent direction and $\alpha_k$ is computed by the standard Wolfe line search. Then

$$\sum_{k \geq 1} \frac{(g_k^T d_k)^2}{\|d_k\|^2} < \infty. \quad (2.5)$$

In the convergence analysis and implementation of conjugate gradient methods, the stepsize $\alpha_k$ is often computed by the strong Wolfe line search, namely, (2.3) and

$$|g(x_k + \alpha_k d_k)^T d_k| \leq -\sigma g_k^T d_k, \quad (2.6)$$

where also $0 < \delta < \sigma < 1$. Dai et al [5] proved the following general convergence result for any conjugate gradient method using the strong Wolfe line search.
Lemma 2.3. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (1.2)–(1.3), where $d_k$ is a descent direction and $\alpha_k$ is computed by the strong Wolfe line search. If
\[ \sum_{k \geq 1} \frac{|g_k^T d_k|^r}{||d_k||^2} = \infty \] (2.7)
for some $t \in [0, 4]$, we have that
\[ \liminf_{k \to \infty} \|g_k\| = 0. \] (2.8)

3. Analyses of general conjugate gradient method

In this section, we will give a general condition on the scalar $\beta_k$, which ensures the global convergence of the nonlinear conjugate gradient method in the case of strong Wolfe line searches. We need the following lemma.

Lemma 3.1. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (1.2)–(1.3), where $d_k$ is a descent direction and $\alpha_k$ is computed by the strong Wolfe line search. If
\[ \sum_{k \geq 1} \frac{|g_k^T d_k|^r}{||d_k||^2} = \infty \] (3.1)
for some $r \in [0, 2]$, the method converges in the sense that (2.8) is true.

Proof. For any $r \in [0, 2]$, if $|g_k^T d_k| > 1$, then we have that $|g_k^T d_k|^r \leq (g_k^T d_k)^2$. It follows that
\[ |g_k^T d_k|^r \leq 1 + (g_k^T d_k)^2 \]
and consequently
\[ \sum_{k \geq 1} \frac{1}{||d_k||^2} \geq \sum_{k \geq 1} \frac{|g_k^T d_k|^r}{||d_k||^2} - \sum_{k \geq 1} \frac{|g_k^T d_k|^2}{||d_k||^2}. \] (3.3)
Therefore by Lemma 2.2, (3.1) and (3.3), we know that (2.7) holds with $t = 0$. Due to Lemma 2.3, (2.8) is true. \qed

The above lemma provides another sufficient condition ensuring the convergence of the nonlinear conjugate gradient method. Combining Lemmas 2.3 and 3.1, we now can prove a more general result.

Corollary 3.2. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (1.2)–(1.3), where $d_k$ is a descent direction and $\alpha_k$ is computed by the strong Wolfe line search. If
\[ \sum_{k \geq 1} \frac{|g_k||g_k^T d_k|^r}{||d_k||^2} = \infty \] (3.4)
for some positive constants $t$ and $r$ satisfying $t + 2r \leq 4$, the method converges in the sense that (2.8) is true.

Proof. Assume that the statement is not true, we have by Lemma 2.3 that
\[ \sum_{k \geq 1} \frac{|g_k||g_k^T d_k|^{t+2r}}{||d_k||^2} < \infty. \] (3.5)
For any $t, r > 0$, if $|g_k^T d_k| \leq \|g_k\|^2$, we have that $\|g_k\| |g_k^T d_k|^{r} \leq \|g_k\|^{t+2r}$; otherwise we have $\|g_k\| |g_k^T d_k|^{r} \leq |g_k^T d_k|^{t+r}$. Therefore the following relation always holds:

$$\|g_k\| |g_k^T d_k|^{r} \leq \|g_k\|^{t+2r} + |g_k^T d_k|^{t+r}. \quad (3.6)$$

By (3.4) and (3.5), we obtain

$$\sum_{k \geq 1} \frac{|g_k^T d_k|^{t+r}}{\|d_k\|^2} = \infty. \quad (3.7)$$

Due to Lemma 3.1 and the fact that $\frac{r}{t} + r \in [0, 2]$, we see that (2.8) holds. Thus we obtain a contradiction. This completes our proof. \(\square\)

In the following, we give a general condition on the scalar $\beta_k$ and show that such a condition can ensure the global convergence of the conjugate gradient method in the case of strong Wolfe line searches. Note that the sufficient descent condition, namely,

$$g_k^T d_k \leq -c\|g_k\|^2 \quad (3.8)$$

for all $k \geq 1$ and some constant $c > 0$, is not revoked in Theorem 3.3.

**Theorem 3.3.** Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (1.2)-(1.3), where $d_k$ is a descent direction and $\alpha_k$ is computed by the strong Wolfe line search. If there exist an infinite subsequence $\{k_i\}$ and a positive constant $c$, such that the values of $\beta_j$ satisfies

$$\prod_{j=i}^{k_i} |\beta_j| \leq c \quad (3.9)$$

for any $i \geq 1$ and $l \leq k_i$, the method converges in the sense that (2.8) is true.

**Proof.** For $k \geq 2$, (3.3) implies that

$$d_k + g_k = \beta_k d_{k-1}. \quad (3.10)$$

Squaring both sides of the above relation, we get that

$$\|d_k\|^2 \leq -2g_k^T d_k + \beta_k^2 \|d_{k-1}\|^2. \quad (3.11)$$

Using (3.11) recursively, we obtain

$$\|d_k\|^2 \leq -2g_k^T d_k - 2 \sum_{j=2}^{k} \prod_{i=j}^{k} \beta_i^2 g_{j-1}^T d_{j-1}, \quad (3.12)$$

which, with condition (3.9), shows that

$$\|d_k\|^2 \leq (1 + c^2) \sum_{j=1}^{k_i} (-2g_j^T d_j). \quad (3.13)$$

If

$$\lim \inf_{i \to \infty} \|d_{k_i}\| < \infty, \quad (3.14)$$

then $\sum_{k \geq 1} \frac{1}{\|d_k\|^2} = \infty$ and hence by Lemma 2.3, (2.8) holds. Otherwise, the following relation holds

$$\lim_{i \to \infty} \|d_{k_i}\| = \infty. \quad (3.15)$$
In this case, it follows from (3.13) and (3.15) that

$$\lim_{i \to \infty} \sum_{j=1}^{k_i} (-g_j^T d_j) = \infty. \quad (3.16)$$

Using relations (3.13) and (3.16) and Lemma 6 in Pu & Yu [18], we can obtain that

$$\lim_{i \to \infty} \sum_{j=1}^{k_i} \frac{-g_j^T d_j}{\|d_j\|^2} = \infty. \quad (3.17)$$

Therefore by Lemma 3.1, we also have (2.8). □

4. Convergence of FR and PRP methods

In this section, we briefly discuss how to use Theorem 3.3 to obtain the global convergence of the FR, and PRP conjugate gradient methods. First, we state the following lemma for the FR method, whose proof can be found in Al-Baali [1].

Lemma 4.1. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider the FR method (1.2), (1.3) and (1.4). If the stepsize $\alpha_k$ is computed by the strong Wolfe line search (2.3) and (2.6) with $\sigma \leq 1/2$, then for all $k \geq 1$,

$$-2\|g_k\|^2 \leq g_k^T d_k < 0. \quad (4.1)$$

Theorem 4.2. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider the FR method (1.2), (1.3) and (1.4). If the stepsize $\alpha_k$ is computed by the strong Wolfe line search (2.3) and (2.6) with $\sigma \leq 1/2$, then the method converges in the sense that (2.8) is true.

Proof. From Lemma 4.1, we know that each $d_k$ is a descent direction. Assume that the convergence relation (2.8) does not hold. Then there exists a positive constant $\gamma$ such that

$$\|g_k\| \geq \gamma, \quad \text{for all } k. \quad (4.2)$$

By the definition (1.4) of $\beta_k^{FR}$, (2.2) and (4.2), we obtain

$$\prod_{j=1}^{k} \beta_j^{FR} = \frac{\|g_k\|^2}{\|g_{k-1}\|^2} \leq \frac{\gamma^2}{\gamma^2} = c. \quad (4.3)$$

Due to Theorem 3.3, (2.8) holds. Therefore we obtain a contradiction. This completes our proof. □

For the PRP method, Powell [15] constructed counter-examples showing that the method may cycle without approaching any solution point. Nevertheless, Gilbert & Nocedal [9] proved that a modification of setting $\beta_k = \max\{\beta_k^{PRP}, 0\}$ results in global convergence. To give another proof to the result by Theorem 3.3, we draw the following lemma from [9].

Lemma 4.3. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (i)-(i) with $\beta_k \geq 0$, where $\alpha_k$ satisfies (2.3), (2.6) and $g_k^T d_{k+1} < 0$. Denote $s_k = x_{k+1} - x_k$ and

$$K_{k,\Delta} = \{i \text{ is an integer : } k \leq i \leq k + \Delta - 1, \|s_{i-1}\| > \lambda\}. \quad (4.4)$$

In this case, it follows from (3.13) and (3.15) that

$$\lim_{i \to \infty} \sum_{j=1}^{k_i} (-g_j^T d_j) = \infty. \quad (3.16)$$

Using relations (3.13) and (3.16) and Lemma 6 in Pu & Yu [18], we can obtain that

$$\lim_{i \to \infty} \sum_{j=1}^{k_i} \frac{-g_j^T d_j}{\|d_j\|^2} = \infty. \quad (3.17)$$

Therefore by Lemma 3.1, we also have (2.8). □

4. Convergence of FR and PRP methods

In this section, we briefly discuss how to use Theorem 3.3 to obtain the global convergence of the FR, and PRP conjugate gradient methods. First, we state the following lemma for the FR method, whose proof can be found in Al-Baali [1].

Lemma 4.1. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider the FR method (1.2), (1.3) and (1.4). If the stepsize $\alpha_k$ is computed by the strong Wolfe line search (2.3) and (2.6) with $\sigma \leq 1/2$, then for all $k \geq 1$,

$$-2\|g_k\|^2 \leq g_k^T d_k < 0. \quad (4.1)$$

Theorem 4.2. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider the FR method (1.2), (1.3) and (1.4). If the stepsize $\alpha_k$ is computed by the strong Wolfe line search (2.3) and (2.6) with $\sigma \leq 1/2$, then the method converges in the sense that (2.8) is true.

Proof. From Lemma 4.1, we know that each $d_k$ is a descent direction. Assume that the convergence relation (2.8) does not hold. Then there exists a positive constant $\gamma$ such that

$$\|g_k\| \geq \gamma, \quad \text{for all } k. \quad (4.2)$$

By the definition (1.4) of $\beta_k^{FR}$, (2.2) and (4.2), we obtain

$$\prod_{j=1}^{k} \beta_j^{FR} = \frac{\|g_k\|^2}{\|g_{k-1}\|^2} \leq \frac{\gamma^2}{\gamma^2} = c. \quad (4.3)$$

Due to Theorem 3.3, (2.8) holds. Therefore we obtain a contradiction. This completes our proof. □

For the PRP method, Powell [15] constructed counter-examples showing that the method may cycle without approaching any solution point. Nevertheless, Gilbert & Nocedal [9] proved that a modification of setting $\beta_k = \max\{\beta_k^{PRP}, 0\}$ results in global convergence. To give another proof to the result by Theorem 3.3, we draw the following lemma from [9].

Lemma 4.3. Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider any method (i)-(i) with $\beta_k \geq 0$, where $\alpha_k$ satisfies (2.3), (2.6) and $g_k^T d_{k+1} < 0$. Denote $s_k = x_{k+1} - x_k$ and

$$K_{k,\Delta} = \{i \text{ is an integer : } k \leq i \leq k + \Delta - 1, \|s_{i-1}\| > \lambda\}. \quad (4.4)$$
Let $|\mathcal{K}^\lambda_{k,\Delta}|$ be the number of elements of $\mathcal{K}^\lambda_{k,\Delta}$. If (4.2) holds, then for any $\lambda > 0$, there exist an integer $\Delta$ and an index $k_0$, such that for any $k \geq k_0$,

$$|\mathcal{K}^\lambda_{k,\Delta}| \leq \frac{\Delta}{2}. \quad (4.5)$$

**Theorem 4.4.** Suppose that $x_1$ is a starting point for which Assumption 2.1 holds. Consider the method (4)-(7) with $\beta_k = \max\{\beta^{PRP}_k, 0\}$, where $\alpha_k$ satisfies (2.3), (2.6) and $g^T_{k+1}d_{k+1} < 0$. Then the method converges in the sense that (2.8) is true.

**Proof.** Assume that (4.2) holds. For

$$\lambda = \frac{\gamma^4}{2L^2\gamma^2}, \quad (4.6)$$

Lemma 4.3 gives an integer $\Delta$ and an index $k_0$ such that (4.5) holds for any $k \geq k_0$. It follows that for any integers $m$ and $k \geq k_0$,

$$|\mathcal{K}^\lambda_{k,m\Delta}| \leq \frac{m\Delta}{2}. \quad (4.7)$$

For any $k \leq i \leq k + m\Delta - 1$, if $i \notin \mathcal{K}^\lambda_{k,m\Delta}$, we have that $\|s_{i-1}\| \leq \lambda$ and hence by (2.1), (2.2) and (4.2),

$$|\beta_i| \leq |\beta^{PRP}_i| \leq \frac{L\gamma^2}{\gamma^2} \leq \frac{\gamma^2}{2\gamma^2}. \quad (4.8)$$

When $i \in \mathcal{K}^\lambda_{k,m\Delta}$, by (2.2) and (4.2), we have that

$$|\beta_i| \leq |\beta^{PRP}_i| \leq \frac{\|g_i\|\|g_{i-1}\|}{\|g_{i-1}\|} \leq \frac{\gamma^2}{\gamma^2}. \quad (4.9)$$

Therefore if we pick

$$c = \left(\frac{2\gamma^2}{\gamma^2}\right)^{\max\{k_0, \Delta\}}, \quad (4.10)$$

for any integers $m$ and $l \leq m\Delta$, we can obtain from (4.7), (4.8) and (4.9) that

$$\prod_{j=1}^{m\Delta} |\beta_j| \leq c. \quad (4.11)$$

Due to Theorem 3.3, (2.8) is true. Therefore we obtain a contradiction. This completes our proof. \qed

## 5. Discussion

We have further studied the general conjugate gradient method using the strong Wolfe line search and provided a condition on the scalar $\beta_k$, namely, (3.9), which guarantees the global convergence of the method in the absence of the sufficient descent condition. Using the result, intuitive proofs have been given to the convergence of the famous FR, and PRP conjugate gradient methods. We believe that our result will lead to a better understanding of already-existing convergence results in the conjugate gradient field and provide a unified tool in the convergence analysis of the conjugate gradient method.
Let us now consider the $n = 2, m = 8$ example of Powell [15]. Assuming that the line search is exact, Powell constructed a two-dimensional function such that the PRP method will cycle near eight points, none of which is a solution point. Direct calculations show that in the example, the limit of $\{\beta_{4j+i} : i = 1, 2, 3, 4\}$ with $j$ is

\[ \frac{2}{3}, \quad 2, \quad \frac{2}{3}, \quad 6 \]

respectively. It follows that

\[ \lim_{j \to \infty} \prod_{i=1}^{4} |\beta_{4j+i}| = 2, \quad (5.1) \]

which implies that the condition (3.9) is not satisfied. Therefore the condition (3.9) cannot be relaxed in certain sense in ensuring the convergence of the nonlinear conjugate gradient method.
